

Ethics-Focused User Metrics: How User Experience Metrics Can Trigger Ethical Design Sensibility

ANONYMOUS AUTHOR(S)

SUBMISSION ID: 5843

Fig. 1. Multi-stage study design and results showing stepwise increase in UX designers' rejection of dark patterns when provided with autonomy-focused evaluation data alongside standard UX metrics. Mixed effects analysis reveals large condition effects ($\chi^2(2) = 32.65, p < 0.001$) with substantial practical differences in design decisions.

How do evaluation frameworks influence designers' ethical decisions? This study investigates how different evaluation data affects designers' willingness to implement design patterns that infringe user autonomy. Through an experiment with 141 UX professionals, we demonstrate that evaluation frameworks systematically guide ethical judgments.

Participants evaluated 15 interfaces under three conditions: no user data, standard UX metrics, or autonomy-focused measures. The evaluation data was real feedback from 126 social media users, and participants were unaware interfaces contained dark patterns. Results showed clear progression: any user feedback increased rejection of problematic designs, but autonomy-focused evaluation nearly doubled rejection rates. Analysis of 1,313 explanations revealed frameworks also changed reasoning patterns, shifting focus from business justifications toward user well-being.

These findings reveal evaluation tools actively shape design ethics. To foster responsible technology, we must equip designers with frameworks that make ethical risks visible.

CCS Concepts: • Human-centered computing → Usability testing; User interface design; • Social and professional topics → Codes of ethics.

Additional Key Words and Phrases: Dark Patterns, Ethics, Manipulation, Social Media, Measuring, User Experience

1 INTRODUCTION

Most technology companies today rely on metrics to organize corporate success and guide design decisions. Nearly all organizations with larger UX departments—from Google's HEART framework [68] to Duolingo's focus on engagement

and learning metrics [63]—have established quantitative measures that their design teams optimize against. These metrics are effective and useful, promising more objective decision-making that enables flat hierarchies and management at scale [72, 82].

Concurrently, the design community has shown sustained interest in ethical aspects of interactive design over recent decades. This is evidenced through value-sensitive design approaches [32], participatory design methods [71], professional ethics tools like conversation cards [35], and privacy-by-design frameworks [17]. One instance of unethical design that is increasingly acknowledged in the UX community is dark patterns—interface elements designed to manipulate user behavior—represent unethical design practices that undermine user autonomy, privacy, and wellbeing [36, 49].

However, a critical gap exists between ethical commitment and standard UX evaluation metrics that lack explicit ethical dimensions. While companies rely heavily on established metrics like the User Experience Questionnaire (UEQ) [45] or System Usability Scale [14], these tools focus primarily on usability and satisfaction without addressing ethical concerns. Research shows that UX professionals often employ “soft resistance” tactics when advocating for ethical design choices that conflict with business goals [84], and product managers face challenges negotiating social values in digital product design [47]. This creates a misalignment where designers committed to ethical practice may not have salient ethical considerations in their evaluation processes.

Our work demonstrates that *metrics make ethical values salient*—and ethically-focused metrics can *trigger ethical sensibility* in design decision-making. To test this hypothesis, we conducted a two-stage study. First, we developed an autonomy-focused evaluation scale by adapting the UEQ with supplementary items specifically designed to capture user reactions to unethical designs. We used a comprehensive taxonomy of dark patterns in social media, derived from academic literature and regulatory guidelines, as ground truth for unethical design practice. In our UX+Autonomy Evaluation Study, 126 social media users evaluated dark pattern interfaces using both standard UEQ metrics and our autonomy-focused scale.

The evaluation data from this UX+Autonomy Evaluation Study was then systematically fed into our main experiment with 141 UX professionals. When these designers were provided with autonomy-focused evaluation data alongside standard UX metrics, they rejected interfaces containing dark patterns at nearly double the rate (56.2% vs. 30.0%). This demonstrates that evaluation metrics are not neutral measurement tools but active design interventions that shape ethical judgment.

This finding has important implications as metrics become increasingly central to design practice. With the rise of automated A/B testing, computational design tools, and AI-driven interface generation, evaluation metrics will likely become even more influential in shaping design outcomes [79]. Our research suggests that incorporating ethical dimensions into these metrics can effectively guide designers toward more ethical decisions—not through external constraint, but by making ethical considerations salient during evaluation.

The paper makes three key contributions: (1) empirical evidence that evaluation metrics actively shape ethical design decisions rather than merely measuring them, (2) demonstration that autonomy-focused metrics can effectively identify manipulative design patterns and influence professional judgment, and (3) practical insights for integrating ethical considerations into existing UX evaluation workflows to support ethical design at scale.

In the subsequent sections, we first explore existing UX metrics and examine how dark patterns are assessed in the literature. We then describe our three-stage methodology: (1) developing an autonomy-focused evaluation scale and a social media dark pattern taxonomy, (2) collecting a perception dataset from social media users, and (3) testing how evaluation data shapes professional design decisions. Finally, we present our findings and discuss their implications for ethical design practice.

105 2 LITERATURE REVIEW**106 2.1 Ethics and Values in Design Practice**

108 **2.1.1 Value-Sensitive Design Approaches.** The design community has demonstrated sustained interest in incorporating
109 ethical considerations into design practice. Value-sensitive design [32] provides frameworks for considering human
110 values throughout the design process. Participatory design approaches [71] emphasize involving stakeholders in design
111 decisions that affect them. Reflective design [73] encourages designers to examine the assumptions and values embedded
112 in their work.

114
115 **2.1.2 Professional Tools for Ethical Design.** Multiple tools have emerged to support ethical design awareness. The
116 Ethical Design Toolkit [35] provides conversation cards to surface ethical considerations during design processes. The
117 Privacy by Design framework [17] offers principles for embedding privacy protection into system architecture. Design
118 ethics games and workshops [25, 52] help teams explore ethical implications of design decisions. Additionally, values in
119 games research [59] provides foundational work for understanding how values are embedded in interactive systems.

121
122 **2.1.3 Challenges in Ethical Design Practice.** Research shows UX professionals often employ 'soft resistance' tactics
123 when advocating for ethical design choices that conflict with business goals [84]. Chivukula et al. [24]'s interview
124 studies with UX practitioners identified five dimensions of design complexity influencing ethical outcomes spanning
125 individual, collaborative, and methodological framing. Karakus et al. [41] explores the ethical dimensions of accessible
126 UX design, highlighting the challenge of balancing stakeholder interests with user intentions, particularly when dark
127 UX patterns are intentionally inserted to manipulate user behavior.

128
129 UX practitioners must develop specific rhetorical strategies to argue for user-centered design decisions [69], demon-
130 strating the systematic organizational pressures that challenge ethical design implementation.

131
132 **2.1.4 The Challenge of Implementation.** However, these tools often operate as separate processes rather than integrated
133 evaluation approaches. They function as add-on considerations rather than core metrics that shape ongoing design
134 decisions and business KPIs. This separation creates a disconnect between ethical awareness tools and the measurement
135 metrics that most directly influence design decisions.

139 2.2 Foundations of User Experience Evaluation

140
141 **2.2.1 Traditional UX Evaluation Methods.** UX evaluation methods aim to quantify good vs. bad design through diverse
142 approaches. According to ISO 9241-210, user experience encompasses "a person's perceptions and responses that result
143 from the use or anticipated use of a product, system or service," including "all the users' emotions, beliefs, preferences,
144 perceptions, physical and psychological responses, behaviours and accomplishments that occur before, during and
145 after use"—explicitly including potential for harm [39]. This comprehensive definition recognizes that user experience
146 extends beyond immediate satisfaction to encompass broader impacts on user wellbeing and autonomy.

147
148 UX evaluation encompasses distinct methodological approaches with different strengths and applications. Jeffries
149 et al. [40] described four major evaluation techniques: heuristic evaluation (expert inspection using systematic criteria),
150 software guidelines (compliance checking against design rules), cognitive walkthroughs (step-by-step task analysis),
151 and usability testing (empirical measurement with real users). These approaches differ fundamentally in their focus:
152 *heuristics* provide systematic inspection criteria for expert evaluation of interface compliance, while *metrics* offer
153 quantitative performance measures, and *qualitative methods* reveal user mental models and subjective experiences [1].

157 Methods range from *IsoMetrics* [34], which focuses on standard compliance, to the *Microsoft Desirability Toolkit* that
158 captures subjective aspects through *Product Reaction Cards* [6]. The *System Usability Scale (SUS)* offers quantitative
159 assessment by scoring system usability from 0 to 100 based on ten statements [14]. Human-Computer Interaction
160 and Human-Robot Interaction fields have many scales available for evaluating subjective human experiences, such as
161 the NASA Task Load Index for workload assessment, but only few address ethical value relevance, as an overview of
162 measurement scales demonstrates [70].
163

164
165
166 2.2.2 *User Experience Questionnaire (UEQ)*. The UEQ assesses users' subjective perceptions using 26 items across
167 six scales: *Attractiveness* (overall impression), *Efficiency*, *Perspicuity*, and *Dependability* (pragmatic qualities), plus
168 *Stimulation* and *Novelty* (hedonic qualities) [45]. Users rate paired adjectives on a -3 to +3 scale.
169

170 The UEQ has achieved widespread adoption, particularly in Europe, with validation in over 30 languages. Since
171 2017, it has surpassed AttrakDiff in usage [26]. Its success stems from free availability, detailed documentation, and
172 business-ready analysis tools. Many professional UX platforms incorporate UEQ as a key metric, and benchmarks allow
173 comparison with common websites and apps [54].
174

175
176
177 2.2.3 *Business Goals and Measurement-Driven Design*. UX designs goal is to align business objectives with user
178 goals [43]. Key Performance Indicators (KPIs) measure progress toward business goals, with UX measures serving
179 as KPIs for holistic design performance [72]. However, as measurements easily become targets [79], it's crucial that
180 business measurements incorporate ethical considerations.
181

182 Research shows UX professionals often employ 'soft resistance' tactics when advocating for ethical design choices
183 that conflict with business goals [84]. Product managers face challenges negotiating social values in digital product
184 design [47], highlighting the tension between business metrics and ethical design. Product managers face challenges
185 negotiating social values in digital product design [47], highlighting the tension between business metrics and ethical
186 design.
187

190 2.3 Dark Patterns and Unethical Design

191 2.3.1 *Defining Dark Patterns*. Dark patterns represent interface design choices that benefit an online service by
192 prioritizing business objectives over user interests, systematically undermining user autonomy, privacy, and well-being
193 [36]. These design practices are characterized by their intentional manipulation of user decision-making through
194 exploiting psychological vulnerabilities and cognitive biases. As Mathur [50] demonstrates, dark patterns engineer
195 users' choice architectures by either modifying the information available to users or by modifying the set of available
196 choices—eliminating and suppressing options that disadvantage the manipulator.
197

198 Their relationship to traditional user experience metrics remains complex and counterintuitive. Calawen [16] found
199 that dark pattern application had no significant effect on overall user experience measurements, with no significant
200 differences observed in UEQ scales of Perspicuity, Efficiency, Dependability, Stimulation, and Novelty, nor in System
201 Usability Scale scores between manipulative and non-manipulative interface versions. This finding suggests that
202 traditional UX evaluation metrics may be fundamentally unable to detect ethical problems in interface design, as
203 manipulative patterns can maintain or even improve conventional usability metrics while undermining user autonomy.
204

209 2.3.2 *User Recognition and Response.* Research shows users can identify dark patterns when asked explicitly. Mildner
210 et al. [56] found that users could distinguish between screenshots containing dark patterns and those without. Bongard-
211 Blanchy et al. [9] found 59% of participants successfully recognized five or more dark patterns among nine interfaces,
212 though some patterns (like confirmshaming) are easier to detect than others (like hidden information).
213

214 2.3.3 *Behavioral Effects of Manipulative Design.* Monge Roffarello and De Russis [58] demonstrated behavioral effects
215 through a 3-week experiment removing social investment displays from Facebook feeds, showing reduced time spent
216 on pages. This aligns with research by Baughan et al. [5] demonstrating that social media design features influence
217 dissociation, affecting users' ability to meaningfully engage with content.
218

219 2.4 The Philosophy and Psychology of Design Influence

220 2.4.1 *Theoretical Frameworks for Design Influence.* In technology design, ethical considerations present complex
221 challenges. Designers develop choice architecture that inevitably influences user behaviors. Drawing a line often, such
222 as between manipulative and persuasive influence, can be hard [77]. This challenge is complicated by the inherent
223 spectrum of behavioral influence that design can exert on users.
224

225 Tromp et al. [80] provide a foundational framework for understanding different types of design influence based on
226 user experience, proposing a classification system built on two critical dimensions: salience (whether the influence is
227 apparent or hidden to the user) and force (whether the influence is strong or weak). Their framework identifies four
228 distinct types of influence: *coercive* (strong and apparent), *persuasive* (weak and apparent), *seductive* (strong and hidden),
229 and *decisive* (weak and hidden). This classification reveals that the ethical implications of design influence depend not
230 only on the intent but also on how users experience and perceive that influence.
231

232 2.4.2 *Manipulation vs. Persuasion.* This theoretical framework illuminates why distinguishing between manipulation
233 and persuasion proves so challenging in practice. As Sánchez Chamorro et al. [77] observe, the boundaries between
234 these concepts are often unclear to practitioners, particularly when design influence operates along gradients of salience
235 and force rather than discrete categories. Alavi [3] argue that by categorizing design patterns into binary "dark" versus
236 "light" categories, we oversimplify the user experience as evil versus moral, when the reality is often more nuanced.
237

238 Contemporary philosophical analysis reveals that manipulation encompasses three primary forms: *bypassing reason*
239 (influences that operate outside conscious rational deliberation), *trickery* (inducing faulty mental states through
240 deception), and *pressure* (exerting non-coercive force through tactics like emotional blackmail or peer pressure) [60].
241 Building on this foundation, Susser et al. [76] define online manipulation as "the use of information technology to
242 covertly influence another person's decision-making, by targeting and exploiting their decision-making vulnerabilities."
243 Contemporary design research has developed frameworks for operationalizing these concepts, with Ahuja and Kumar
244 [2] proposing methods for evaluating dark patterns from an autonomy perspective.
245

246 2.4.3 *Cognitive and Philosophical Perspectives.* Perhaps most significantly for design professionals, philosophical
247 analysis reveals that manipulation can occur even when the manipulator lacks conscious intent to manipulate—people
248 can "behave manipulatively despite consciously intending not to" [60]. This observation aligns with Sánchez Chamorro
249 et al. [77]'s finding that "designers are not moral philosophers, and, although they have an intuition, we cannot always
250 expect them to make a complete assessment of the ethical aspects of designs."
251

252 The challenge of defining ethical boundaries in design is further complicated by the concept of "interpersonal
253 justification" [42], which suggests that design choices must be justifiable to those affected by them. A foundational
254

challenge emerges from the lack of consensus among UX professionals about core concepts in the field itself. Lallemand et al. [44] conducted an international survey of 758 practitioners, revealing significant differences in how UX is understood and practiced, with findings indicating that "despite many attempts to understand, define and scope UX, one may still wonder whether a consensus has been reached on this concept."

The manipulation of user behavior through dark patterns is well-documented, with studies showing how certain design choices influence user consent practices against their preferences [8].

2.5 Professional Practice and Ethical Decision-Making

2.5.1 *Ethical Reasoning Patterns in UX.* Research reveals systematic patterns in how UX professionals approach ethical decision-making that illuminate fundamental challenges in evaluation metrics. Sánchez Chamorro et al. [77] conducted an extensive investigation of ethical tensions in UX design practice, finding that professionals consistently invoke principles of "trust, transparency, and user autonomy" as guiding values, yet often fail to implement these principles due to contextual pressures and organizational constraints.

This research reveals a critical phenomenon of "ethical blindness" where designers create problematic designs unintentionally, not through malicious intent but through systematic limitations in their decision-making processes. The concept of ethical blindness, as defined by Palazzo et al. [62], suggests that "people might behave unethically without being aware of it" due to "a complex interplay between individual sense making activities and context factors." Research on design student behavior provides empirical evidence for this phenomenon, with Chivukula et al. [20] finding that while design students demonstrated sensitivity toward user values, they often contradicted these values through tacit intentions to persuade users in order to achieve stakeholder goals.

2.5.2 *Organizational Challenges and Responsibility.* UX professionals frequently "rely on other roles which hold the 'ethics ownership': business, managerial or legal departments" [77], raising fundamental questions about responsibility attribution in design processes. This tendency toward responsibility diffusion becomes particularly problematic in light of legal scholarship demonstrating that dark patterns constitute "disloyal design"—a form of wrongful self-dealing that takes advantage of design affordances to the detriment of vulnerable users [38].

The research acknowledges that "designers are not moral philosophers, and, although they have an intuition, we cannot always expect them to make a complete assessment of the ethical aspects of designs" [77].

2.5.3 *Cognitive Limitations and Evaluation Tools.* While empirical evidence in Human Computer Interaction research is scarce, Farzandipour et al. [29]'s controlled comparison of Heuristic Evaluation versus Cognitive Walkthrough found that evaluation method choice fundamentally altered evaluator reasoning patterns: HE identified 104 unique problems versus CW's 24, with only 33.3% overlap and completely different severity patterns. HE evaluators focused on effectiveness and satisfaction while CW evaluators emphasized learnability and efficiency—clear evidence that evaluation methods shape professional attention and judgment.

Evidence from adjacent professional domains demonstrates that assessment metrics fundamentally alter reasoning patterns and judgment priorities. Meta-analyses across medicine, education, and clinical psychology consistently demonstrate that structured assessment metrics outperform holistic professional judgment, with studies showing statistical methods superior to clinical intuition across 136 studies [7, 53]. Lens Model Theory explains how assessment metrics act as cognitive filters, systematically weighting available information to create predictable judgment patterns [15]. The psychological foundation for these effects lies in bounded rationality [74], which recognizes that professionals operate

313 under cognitive limitations and rely on heuristics for decision-making. Recent HCI research has begun examining how
314 cognitive biases affect human-computer interaction [10].
315

316 2.6 Current Approaches to Ethical Evaluation

317 2.6.1 *Existing Ethical Assessment Tools.* Although instruments like the Ethical Climate Questionnaire exist to assess
318 organizational ethics [64] and tools like the Facebook Addiction Questionnaire gauge individual platform depen-
319 dependency [28], these only yield data on business organization and individual human long-term effects. More concretely,
320 some researchers have proposed 'moral cards', designed for designers to use as a reflective tool on adhering to ethics by
321 design [25].
322

323 The proliferation of ethical design methodologies has become extensive, with comprehensive guides offering
324 hundreds of techniques for becoming more ethically aware and responsible in design practice [21], and systematic
325 surveys documenting 63 existing methods intentionally designed for ethical impact [22]. In artificial intelligence,
326 considerable efforts have been made to incorporate ethics, though a review indicates that these tools investigate ethics
327 narrowly, focusing on a few dimensions rather than examining all aspects holistically [65].
328

329 A notable attempt to quantify dark patterns specifically is the System Darkness Scale, which provides a targeted
330 25-item checklist to evaluate whether software employs specific dark pattern elements [81]. While this tool offers
331 valuable insights into dark pattern detection, it focuses specifically on those design elements rather than broader ethical
332 considerations in user interfaces.
333

334 2.6.2 *Methodological Challenges.* Efforts to develop tools for evaluating persuasive potential face considerable obstacles.
335 Meschtscherjakov et al. [55] developed the Persuasive Potential Questionnaire (PPQ) to measure persuasive influence
336 across five dimensions, but acknowledge significant challenges and drawbacks in creating generic, context-independent
337 measures of persuasive effects. Their work highlights the fundamental difficulty of standardizing ethical evaluation
338 measures across diverse interface contexts.
339

340 Chamorro and Lallemand [18] identify the need for new research approaches to study manipulative design effects,
341 noting limitations in current methods for measuring the impact of deceptive interfaces on users. These methodological
342 challenges are compounded by the inherent ethical implications of evaluation methods themselves, as Williamson
343 and Sundén [83] demonstrate that research methodologies in HCI carry ethical dimensions that may influence design
344 practices in unintended ways.
345

346 Some researchers have explored alternative evaluation paradigms that move beyond traditional efficiency-focused
347 metrics. Lu et al. [48] propose focusing on user empowerment measures rather than engagement metrics when evaluating
348 responses to dark patterns, emphasizing awareness-raising and enabling user action against manipulative designs.
349 Similarly, Odom et al. [61] extend slow technology theory to propose evaluation criteria based on meaningful interaction
350 and reflection rather than speed and efficiency.
351

352 2.6.3 *The Research Gap.* Despite extensive research on ethical design tools and widespread recognition of dark patterns
353 as problematic, unethical design practices continue to proliferate across digital platforms [13]. This persistence occurs
354 not due to lack of ethical awareness or available tools, but suggests a more fundamental issue: the evaluation metrics
355 that drive design decisions may themselves promote unethical outcomes.
356

357 The evidence points to a critical gap in understanding how measurement shapes design practice. While Brignull
358 [11, 12] warned early that metric-driven design could inadvertently encourage manipulative practices, and Thomas
359 and Umansky [79] demonstrated how "measurements become targets," no empirical research has examined whether
360

365 evaluation metrics themselves influence ethical reasoning in design teams. This represents a significant oversight, given
366 extensive evidence from adjacent professional domains that assessment tools fundamentally alter judgment patterns
367 and decision priorities [7, 15, 53].

368 The research void is particularly striking given that HCI has produced robust empirical research on professional
369 moral reasoning in UX practice [23, 33, 77], yet none of this work examines how the evaluation methodologies
370 themselves shape ethical decision-making. If evaluation metrics act as cognitive filters that systematically weight
371 different considerations [15], then the choice of measurement approach may fundamentally determine whether ethical
372 concerns become salient during design processes.

373 Our work addresses this gap by providing the first empirical investigation into how different UX evaluation metrics
374 influence ethical reasoning patterns in design practice. Rather than developing new ethical tools, we examine whether
375 the measurement approaches that most directly drive design decisions can be configured to promote more ethical
376 outcomes.

380 3 METHOD

381 This study employed a multi-stage research design to investigate how autonomy-focused evaluation data influences UX
382 designers' decisions regarding interfaces containing dark patterns. The research comprised three sequential stages: (1)
383 taxonomy development and interface creation, (2) UX+Autonomy Evaluation Study with social media users to establish
384 evaluation benchmarks, and (3) main experiment with professional UX designers.

385 **Ethics Approval:** The main experiment received IRB approval as exempt research and followed informed consent
386 protocols, participant debriefing, and voluntary participation procedures. The UX+Autonomy Evaluation Study followed
387 university ethics guidance including informed consent and did not require formal IRB approval.

393 3.1 Stage 1: Dark Pattern Taxonomy Development

394 We developed a comprehensive taxonomy of social media dark patterns through systematic literature review and
395 integration of existing taxonomies. Following established approaches for taxonomy development [36], we combined
396 findings from two peer-reviewed academic papers [57, 58] and the European Data Protection Board regulatory guidelines
397 [27].

398 Our consolidation process involved: (1) gathering dark pattern types from the three source taxonomies, (2) removing
399 duplicates, (3) merging similar patterns with consistent definitions, and (4) organizing patterns into strategic categories
400 based on manipulation mechanisms. This process yielded 15 distinct low-level dark patterns organized under six
401 high-level strategic categories aligned with Gray et al.'s authoritative framework [37]: *Nagging, Obstruction, Sneaking,*
402 *Interface Interference, Forced Action, and Social Engineering*.

403 The complete taxonomy comprises: **Nagging** (Nagging), **Obstruction** (Overcomplicated Process, Hindering Account
404 Deletion), **Sneaking** (Sneaking Bad Default, Expectation Result Mismatch), **Interface Interference** (False Hierarchy,
405 Trick Wording, Toyng with Emotion), **Forced Action** (Forced Access), and **Social Engineering** (Gamification, Social
406 Pressure, Social Connector, Content Customization, Endlessness, Pull to Refresh).

407 High-fidelity interface mockups were created for each pattern using a consistent minimalistic social media application
408 design framework. Each mockup presented a specific dark pattern within realistic social media contexts, recreated
409 based on examples provided in the source taxonomies where available, ensuring ecological validity while maintaining
410 experimental control across stimuli.

Table 1. Complete Taxonomy of 15 Dark Patterns in Social Media

High-Level Strategy	Low-Level Pattern	Source Patterns	Definition
Nagging	Nagging	Continuous Prompting [27]	Situations where users are annoyed by repeated attempts to get them to do something they did not intend to
Obstruction	Overcomplicated Process	Longer Than Necessary, Lacking Hierarchy, Too Many Options, Privacy Maze, Labyrinth [27, 57]	Processes intentionally designed to be complicated by adding unnecessary steps, too many options, or lack of clear hierarchy
	Hindering Account Deletion	Clinging to accounts, Forced Grace Period [57]	Difficulties encountered by users while attempting to (immediately) delete their social media accounts
Sneaking	Sneaking Bad Default	Auto Accept Third Party Terms, Deceptive Snugness [27, 57]	Instances where default selections are made by platforms to serve their own interests, possibly without users' awareness
	Expectation Result Mismatch	Misleading action, Plain Evil, Dead end, Decontextualising, Inconsistent Interface [27, 57]	Situations where users expect a specific outcome but receive a different result
Interface Interference	False Hierarchy	Hidden in Plain Sight, Look over there, Reduced Friction [27, 57]	Designs that form users' choice by enticing attention away from undesired options to platform's preferred ones
	Trick Wording	Language discontinuity, Ambiguous wording, Conflicting information [27]	Inappropriate language used to confuse users, leaving them in misunderstanding
	Toying with Emotion	Emotional Steering, Persuasive Language [27, 57]	Situations where emotions are used to steer users' decisions in a particular direction
Forced Action	Forced Access	Forced Access Granting [57]	Instances where users are forced to give access to something to continue getting to their initial goal
	Gamification	Gamification, Social Investment [57, 58]	Situations where rewards are used, pressuring users to continue using the platform to not lose achieved progress
Social Engineering	Social Pressure	Fear Of Missing Out, Regression Toward The Mean [57]	Instances where users are pressured to visit the platform to avoid missing out on important topics
	Social Connector	Social Connector [57]	Situations where users are prompted to provide information about friends or invite them to expand their network
	Content Customization	False Content Customisation, Recommendations [57, 58]	Customizing content to manipulate users through falsified or overly precise customization
	Endlessness	Infinite Scrolling, Autoplay [57, 58]	Endlessly and automatically loading content, eliminating need for user decision-making
	Pull To Refresh	Pull To Refresh [57, 58]	Functionality that requires users to pull on the interface to reload the page

469 3.2 Stage 2: UX+Autonomy Evaluation Study - User Evaluation of Dark Patterns

470 3.2.1 *Participants.* A total of 126 social media users partic-
 471 ipated in the UX+Autonomy Evaluation Study to establish
 472 baseline user perceptions of the dark pattern interfaces.
 473 Participants were recruited through convenience sampling
 474 via social media platforms (Facebook groups), survey ex-
 475 change platforms (SurveyCircle), and snowball sampling
 476 within research networks. The sample comprised 53 females
 477 (42%) and 73 males (58%), with ages ranging from 19 to 80
 478 years. Seventy-five percent resided in Austria, with addi-
 479 tional participants from the United States (9%), Switzerland
 480 and Germany (5%), and other locations (11%). Eighty-seven
 481 percent considered themselves at least somewhat techni-
 482 cally savvy (56% responding "Yes" and 31% responding "A
 483 bit" to technical savviness).

484 3.2.2 *Instrumentation.* We adapted the User Experience
 485 Questionnaire (UEQ) to include ethical evaluation dimen-
 486 sions through an iterative development process. The adap-
 487 tation involved: (1) reviewing all 26 UEQ adjective pairs
 488 for applicability to dark pattern evaluation, (2) identifying
 489 items likely to elicit strong participant responses, and (3)
 490 adding four autonomy-focused items addressing manip-
 491 ulation techniques.

492 The autonomy-focused items were developed through
 493 a systematic process involving autonomy literature review
 494 and expert consultation. Three dark pattern experts with
 495 backgrounds in HCI ethics, manipulation theory, and user
 496 autonomy research collaboratively developed contrasting
 497 autonomy elements based on established frameworks for
 498 user agency and freedom from manipulation. The expert
 499 team reviewed autonomy literature to identify key dimen-
 500 sions of user control, transparency, and freedom from
 501 coercive influence, drawing particularly on Tromp et al.'s
 502 framework of design influence salience and force [80], Nog-
 503 ggle's philosophical analysis of autonomy-preserving versus
 504 autonomy-undermining influence [60], Susser et al.'s defini-
 505 tion of online manipulation through covert decision-making
 506 exploitation [76], and Ahuja et al.'s methods for evaluating
 507 dark patterns from an autonomy perspective [2]. These theoretical
 508 constructs were translated into semantic differential
 509 pairs suitable for the UEQ format.

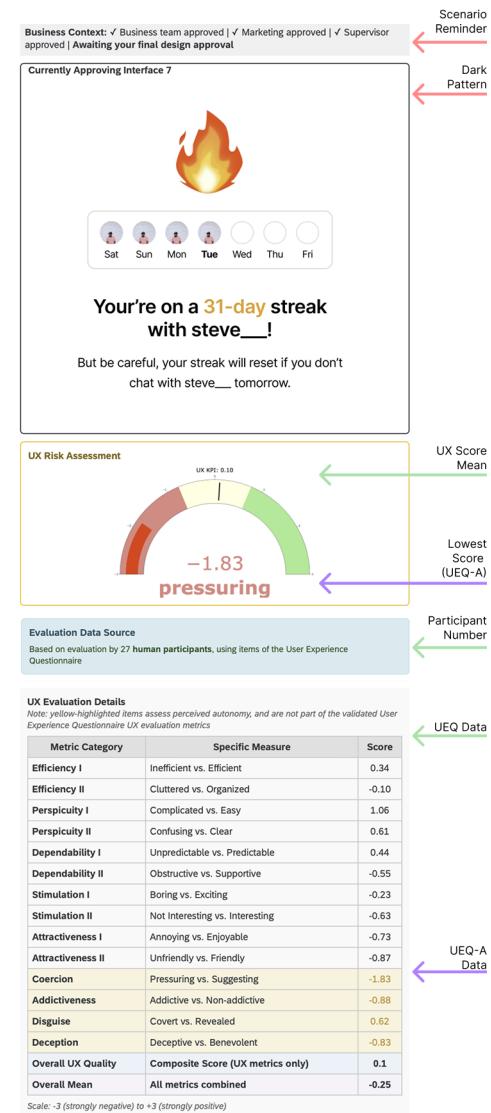

Fig. 2. Example stimuli showing the three experimental conditions. • Baseline condition shows the interface and business context presented to all participants. • UEQ condition shows additional UEQ evaluation data including gauge with UX score mean and detailed UEQ evaluation data with participant numbers. • UEQ-A condition shows additional UEQ-A autonomy data with the lowest autonomy score highlighted.

521 The final instrument comprised 14 items: 10 items forming 5 two-item scales from the UEQ-S (UEQ short version)
522 excluding Novelty—specifically Perspicuity, Efficiency, Dependability, Stimulation, and a two-item Attractiveness
523 scale—plus 4 standalone manipulation-focused items: *pressuring / suggesting, addictive / non-addictive, covert / transparent,*
524 and *deceptive / benevolent.*

525
526 3.2.3 *Procedure.* Each enduser participant evaluated 5 randomly selected dark pattern interfaces from the complete
527 set of 15 patterns using 7-point semantic differential scales (-3 to +3) consistent with standard UEQ methodology. To
528 prevent survey fatigue, participants saw only 5 of the 15 patterns rather than the complete set. A "don't know/not
529 applicable" option was provided for each item, and item order was randomized with balanced positive/negative term
530 presentation.
531

532 This UX+Autonomy Evaluation Study generated the user evaluation data that formed the basis for the experimental
533 manipulations in the main study, ensuring that evaluation summaries presented to designers were grounded in actual
534 user perceptions rather than researcher-generated content. Key findings showed that dark patterns were perceived as
535 pressuring, annoying, and unfriendly, with *Forced Access* rated worst among all patterns.
536

537 3.3 Stage 3: Main Experiment - Designer Decision-Making

538 3.3.1 *Participants.* A total of 141 UX/design professionals participated in the main three-condition experiment following
539 a power analysis indicating a target recruitment of 140 participants. Participants were randomly assigned to one of
540 three between-subjects conditions: UEQ evaluation data only ($n = 49$), UEQ + Autonomy-focused evaluation data ($n =$
541 47), or No evaluation data baseline ($n = 45$).
542

543 **Recruitment and Compensation:** Participants were recruited through Prolific Academic with pre-screening
544 requirements including: (1) professional experience in UI/UX design, product design, or design decision-making roles,
545 (2) minimum 1 year of professional design experience, and (3) fluency in English. Additional Prolific pre-screening
546 limited recruitment to participants indicating knowledge of software development techniques, responsive design, UI
547 design, A/B testing, and UX methodologies. Participants were compensated based on Prolific's \$12/hour guideline for
548 an estimated 20-minute study, but median completion time was 30 minutes, resulting in an average compensation rate
549 of \$8.06/hour.
550

551 3.3.2 *Design and Procedure.* Participants were randomly assigned to one of three between-subjects conditions manipulating
552 the type of evaluation information presented alongside interface designs:
553

- 554 • **UI condition (baseline):** Participants evaluated interfaces without any user feedback information, providing a
555 control condition for intrinsic design assessment.
556
- 557 • **UEQ condition:** Participants viewed standardized user evaluation summaries based on the User Experience
558 Questionnaire [45], focusing on pragmatic and hedonic quality dimensions derived from the Stage 2
559 UX+Autonomy Evaluation Study.
560
- 561 • **UEQ-A condition:** Participants viewed the same UEQ summaries plus additional autonomy-focused evaluation
562 data emphasizing perceived coercion, perceived addiction, perceived disguise, and perceived deception also
563 derived from the Stage 2 UX+Autonomy Evaluation Study.
564

565 **Evaluation Data Presentation:** In the UEQ and UEQ-A conditions, evaluation data was presented as realistic user
566 feedback summaries alongside each interface. The display included: (1) an overall mean UEQ score gauge showing
567 the aggregate rating across all UEQ-S dimensions, (2) a detailed breakdown table showing individual subscale scores
568

for Perspicuity, Efficiency, Dependability, Stimulation, and Attractiveness, and (3) in the UEQ-A condition only, an additional section highlighting the lowest-ranking autonomy-related item from among the four manipulation-focused measures (*pressuring, addictive, covert, deceptive*). Since the autonomy items were standalone measures rather than forming an aggregate scale, we presented the most problematic individual item to maximize ecological validity while avoiding misleading aggregation across conceptually distinct autonomy dimensions.

The evaluation data was presented in a professional business dashboard format including: (1) a business approval context header to simulate realistic organizational decision-making scenarios for a social media startup, (2) a "UX Risk Assessment" section containing the gauge visualization showing the overall UEQ mean score with color coding (red for negative, yellow for neutral, green for positive ratings), and (3) a detailed data table presenting individual metric scores on the -3 to +3 scale consistent with standard UEQ methodology. All evaluation data was derived from the Stage 2 UX+Autonomy Evaluation Study ensuring ecological validity, with sample sizes clearly indicated (ranging from 23-47 participants per interface depending on the randomization scheme used in the UX+Autonomy Evaluation Study).

Each participant evaluated 10 interfaces randomly selected from the set of 15 dark pattern interfaces developed in Stage 1. The interfaces were presented within a realistic business approval context to simulate authentic decision-making scenarios in a social media startup environment.

For each interface, participants completed two primary dependent measures and two secondary measures providing contextual insight. **Primary dependent measures:** (1) release tendency ("How likely would you be to release this interface design?") rated on an 8-point Likert scale (0 = *definitely would not release* to 7 = *definitely would release*), and (2) a binary release decision ("Would you release this interface design?" yes or no). **Secondary measures:** (3) a written explanation ("Please explain your decision") providing qualitative insight into reasoning patterns, and (4) decision confidence ("How confident are you in the decision you just made?") rated on an 8-point scale (0 = *completely uncertain* to 7 = *completely certain*).

3.3.3 Participant Characteristics. All participants reported professional experience in UI/UX design, product design, or design decision-making roles meeting Prolific's pre-screening requirements. Following completion of the main experimental task, participants provided demographic information about their professional backgrounds. Participants represented diverse professional backgrounds, with UX/UI Designers (52.0%) being the most common role, followed by Design Managers and Product Managers (12.0% each), UX Researchers (7.0%), Product Designers (6.0%), and Design Directors (3.0%). The remaining 8.0% reported other design-related roles. Professional experience exceeded minimum requirements with substantial representation across experience levels.

Design Decision Authority: Participants demonstrated substantial decision-making authority within their organizations, with 75.0% holding either final decision authority (29.0%) or significant influence (46.0%) over interface design decisions in their current roles. Only 20.0% reported some input, 4.0% reported little input, and 1.0% reported no decision authority.

Dark Pattern Domain Knowledge: The sample demonstrated strong familiarity with dark pattern concepts, with 77.0% reporting some level of familiarity (38.0% very familiar, 39.0% somewhat familiar), 19.0% slightly familiar, and only 5.0% unfamiliar. This domain knowledge distribution indicates appropriate professional qualification for the experimental task.

Data Quality and Final Sample: Eleven participants were excluded from analysis due to suspicious response patterns identified through both automated screening and manual review of professional explanations. This quality

625 assurance process resulted in a final analytical sample of 141 participants with verified professional qualifications and
626 engaged participation.
627

628 3.4 Statistical Analysis 629

630 We conducted statistical analysis at two levels to capture both participant-level patterns and per-evaluation effects:

631 **Participant-level analysis:** For rejection rates, we calculated mean rejection rates for each participant across their
632 evaluated interfaces and conducted one-way ANOVA with planned contrasts and Tukey's HSD post-hoc tests. This
633 approach addresses the nested structure while meeting normality assumptions for binary outcome aggregation.
634

635 **Per-evaluation mixed effects analysis:** For release tendency, we employed mixed effects modeling to analyze
636 individual evaluation responses while accounting for participant and interface random effects. This approach treats each
637 interface evaluation as an independent observation while controlling for non-independence due to repeated measures
638 within participants and across interfaces. Mixed effects models used maximum likelihood estimation with condition as
639 fixed effect and participant and interface as random effects.
640

641 **Interface-level analysis:** Individual interface effects were examined using planned contrasts between UEQ and
642 UEQ-A conditions with false discovery rate (FDR) correction for multiple comparisons across the 15 interfaces. This
643 focused comparison was theoretically motivated by our specific hypothesis that autonomy-focused evaluation metrics
644 would enhance designers' sensitivity to manipulative design elements compared to standard usability metrics, making
645 the UEQ vs UEQ-A contrast the most theoretically relevant for understanding evaluation framework effects on dark
646 pattern detection.
647

648 **Confidence analysis:** Decision confidence was analyzed using mixed effects modeling parallel to the tendency
649 analysis, with participant and interface random effects.
650

651 All analyses were conducted in R (version 4.4.2) with significance set at $\alpha = .05$.
652

653 3.5 Text Analysis of Professional Explanations 654

655 To analyze the justification patterns underlying design decisions, we employed computational text analysis combining
656 initial LDA topic modeling with hypothesis-driven theme refinement. We developed eight justification categories:
657 Manipulation Awareness, Responsibility Avoidance, Ethics-Focused Reasoning, Aesthetic-Focused Reasoning, Business-
658 Focused Reasoning, Emotional Intensity, Conformity Justification, and Interface Design Elements. For each justification
659 category, we performed binary classification of explanations (justification present/absent) and conducted chi-square
660 tests with Bonferroni correction ($\alpha = 0.00625$) and Cramér's V effect sizes. Complete methodological details, keyword
661 lists, and validation procedures will be available in the OSF repository [4].
662

664 3.6 Materials and Stimuli 665

666 *3.6.1 Dark Pattern Interface Development.* The study used 15 social media dark patterns identified through systematic
667 literature review combining peer-reviewed papers and regulatory documents. These patterns were categorized under
668 six distinct strategies: nagging, forced action, obstruction, interface interference, sneaking, and social engineering. Each
669 pattern was recreated as a high-fidelity visual mockup in a minimalistic social media app design framework, ensuring
670 consistency while highlighting specific manipulative mechanisms.
671

672 Interface mockups were designed to represent realistic social media contexts including user profiles, feeds, settings
673 pages, and notification systems. Each interface prominently featured the target dark pattern while maintaining visual
674 consistency through a unified design system including consistent typography, color palette, iconography, and layout
675
676

677 structure. This approach ensured that differences in participant responses could be attributed to the specific dark pattern
678 mechanisms rather than confounding visual design differences.
679

680 **3.6.2 Evaluation Data Generation.** The evaluation data presented to participants in the UEQ and UEQ-A conditions
681 was derived from the Stage 2 UX+Autonomy Evaluation Study with 126 social media users who evaluated these same
682 interfaces using an extended User Experience Questionnaire. Standard UEQ summaries focused on traditional usability
683 and hedonic quality metrics, while UEQ-A summaries additionally highlighted autonomy-related concerns including
684 user control, transparency, and freedom from manipulation. This data formed the basis for both experimental conditions,
685 ensuring ecological validity of the evaluation information.
686

687 In the UEQ condition, participants viewed standardized evaluation summaries presenting six core UEQ dimensions
688 (Attractiveness, Perspicuity, Efficiency, Dependability, Stimulation, and Novelty) with mean scores and confidence
689 intervals. The UEQ+Autonomy condition presented identical UEQ data plus four additional autonomy-focused dimensions
690 (pressuring vs. suggesting, addictive vs. non-addictive, covert vs. revealed, deceptive vs. benevolent) highlighted
691 to emphasize user control and freedom from manipulation. All evaluation data was presented in consistent table
692 format with scores normalized on a 7-point scale, ensuring comparable information density across conditions while
693 manipulating the ethical salience of the feedback.
694

695 4 RESULTS

696 4.1 UX+Autonomy Evaluation Study: Data Generation

697 The UX+Autonomy Evaluation Study with 126 social media users successfully generated the evaluation dataset used in
698 the main experiment. As detailed in Appendix Table 2, the 15 dark pattern interfaces showed varied user perceptions
699 across both standard UEQ dimensions and autonomy-focused measures. Forced Access received the most negative
700 overall evaluation (Mean = -0.90), while Pull to Refresh was rated most positively (Mean = 0.49). The autonomy-focused
701 items effectively differentiated manipulative patterns, with Nagging, False Hierarchy, and Gamification showing the
702 strongest negative responses on pressuring vs. suggesting measures. This UX+Autonomy Evaluation Study provided
703 ecologically valid evaluation summaries for the subsequent designer decision-making experiment. More detailed analysis
704 of the UX+Autonomy Evaluation Study can be found in our workshop paper (ANONYMIZED). Complete datasets will
705 be made available through the Open Science Framework upon publication, and descriptive statistics are provided in the
706 appendix.
707

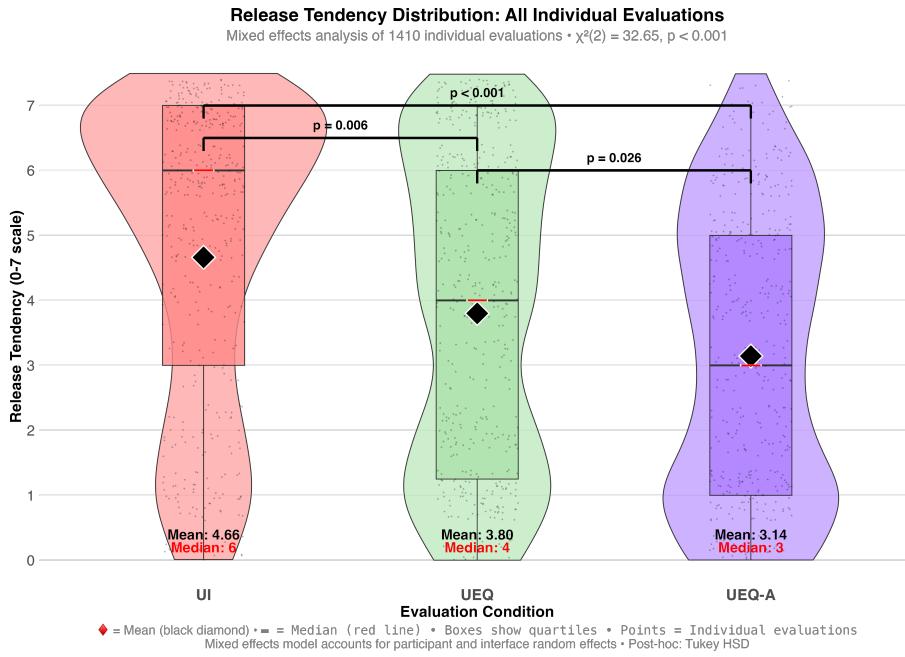

708 4.2 Main Study: Effects of Evaluation Condition on Designer Decisions

709 Analysis revealed significant differences between evaluation conditions for both dependent variables, confirming our
710 hypotheses about the influence of evaluation frameworks on design decision-making.
711

712 **4.2.1 Release Tendency.** Mixed effects analysis accounting for participant and interface random effects revealed
713 significant differences in release tendency between evaluation conditions, $\chi^2(2) = 32.65, p < .001$. This analysis treats
714 each interface evaluation as an independent observation ($N = 1,410$ evaluations from 141 participants across 15 interfaces)
715 while controlling for the nested structure of multiple evaluations per participant and per interface.
716

717 Post-hoc comparisons using estimated marginal means with Tukey adjustment confirmed our hypothesized pattern:
718 participants in the UI (no evaluation data) condition showed significantly higher release tendency ($M = 4.66, SE = 0.31$)
719 compared to both the UEQ condition ($M = 3.81, SE = 0.31$), $p = .006$, $d = 0.37$, and the UEQ-A condition ($M = 3.12, SE =$
720

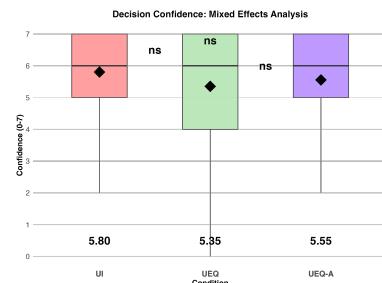

729 0.31), $p < .001$, $d = 0.67$. Additionally, the UEQ condition showed significantly higher release tendency than the UEQ-A
 730 condition, $p = .026$, $d = 0.29$.
 731

755 Fig. 3. Release tendency by evaluation condition. Participants rated their tendency to release each interface on a 0-7 scale (0 =
 756 *definitely would not release*, 7 = *definitely would release*). Participants showed systematically different judgments depending on the
 757 evaluation framework provided, with autonomy-focused evaluation data leading to significantly more critical assessments. Error bars
 758 represent 95% confidence intervals.

760
 761 **4.2.2 Rejection Rates.** Participant-level analysis of rejection rates revealed
 762 the hypothesized reversed pattern. One-way ANOVA of participant mean
 763 rejection rates showed significant between-group differences, $F(2, 138) =$
 764 15.97, $p < .001$, $\eta^2 = .188$. Post-hoc comparisons using Tukey's HSD con-
 765 firmed significant differences between all conditions: UEQ-A participants
 766 rejected significantly more interfaces ($M = 56.2\%$, $SD = 21.3\%$) compared
 767 to UEQ participants ($M = 43.9\%$, $SD = 19.9\%$), $p = .021$, $d = 0.60$, and UI
 768 participants ($M = 30.0\%$, $SD = 25.3\%$), $p < .001$, $d = 1.13$. UEQ participants
 769 also rejected significantly more interfaces than UI participants, $p = .008$, d
 770 = 0.62.

773
 774 **4.2.3 Decision Confidence.** Analysis of participants' confidence in their
 775 release decisions revealed a striking pattern: despite the significant behav-
 776 ioral differences observed in release tendency and rejection rates, confi-
 777 dence ratings remained consistently high across all conditions with no sig-
 778 nificant differences. Mixed effects analysis accounting for participant and inter-
 779 face random effects found no significant condition effect, $\chi^2(2) = 4.26$, $p = .119$.

780 Fig. 4. Decision confidence remained consist-
 781 ently high across all conditions (0 = *not at all*
 782 *confident*, 7 = *extremely confident*), despite sig-
 783 nificant behavioral differences in release deci-
 784 sions.

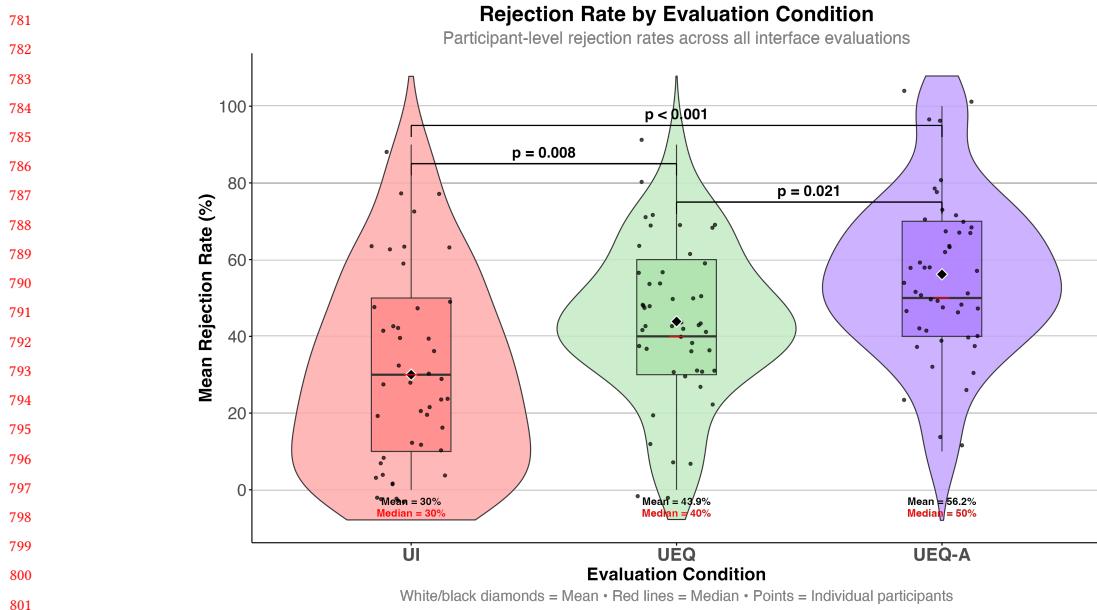

Fig. 5. Rejection rates by evaluation condition. These rates represent the percentage of interfaces each participant rejected across their 10 evaluated interfaces, based on their binary yes/no release decisions. Participants who received autonomy-focused evaluation data rejected significantly more interfaces containing dark patterns. Error bars represent 95% confidence intervals.

Mean confidence ratings on the 0-7 scale (0 = *completely uncertain*, 7 = *completely certain*) regarding their binary release decisions were: No Evaluation Data condition ($M = 5.80$, $SD = 0.16$), UEQ condition ($M = 5.35$, $SD = 0.15$), and UEQ+Autonomy condition ($M = 5.55$, $SD = 0.15$). All post-hoc comparisons were non-significant (all $p > .10$), with median confidence ratings of 6 across all conditions, indicating high confidence regardless of the evaluation information provided.

This pattern suggests systematic overconfidence in design decision-making: participants remained equally confident in judgments that were demonstrably different when provided with additional evaluation information, revealing a disconnect between decision confidence and decision quality.

4.3 Justification Pattern Analysis

Computational text analysis of 1,313 professional explanations revealed differences in justification patterns across evaluation frameworks. Seven of eight justification categories showed condition differences after Bonferroni correction ($p < 0.00625$), with effect sizes ranging from small to medium (Cramér's V: 0.107 to 0.299). These justification categories were informed by initial LDA topic modeling, which identified foundational categories including business approval processes, visual design aesthetics, and usability considerations, with subsequent hypothesis-driven refinement to capture nuanced ethical justification patterns.

4.3.1 Manipulation Awareness. The UEQ-A condition increased manipulation awareness ($\chi^2 = 117.1$, $p < 0.001$, $V = 0.299$). Manipulation awareness was present across all conditions: UEQ-A (77.7%), UI (20.7%), and UEQ (1.7%).

833 Examples from UI condition included direct statements like “too pushy” and “it is very manipulative,” with participants
834 identifying “emotionally coercive language” and designs that “feels off” with a “warning tone.”
835

836 UEQ-A participants frequently referenced specific metrics: “coercion score is extremely poor (-1.83), suggesting users
837 feel pressured” and identifying designs as “pressuring or manipulative, potentially harming users.”
838

839 **4.3.2 Responsibility Avoidance.** The UI condition promoted responsibility avoidance patterns ($\chi^2 = 42.6$, $p < 0.001$, $V =$
840 0.180), with 70.4% of responsibility avoidance instances occurring in UI compared to 18.5% in UEQ-A and 11.1% in UEQ.
841

842 UI participants frequently cited organizational approval: “business team, marketing department, and my supervisor
843 have all approved,” “already approved by all other parties,” and “all key teams” approval. They expressed concerns about
844 “professional and business risk,” “competitive market” with “limited runway,” and emphasized “momentum,” “resources
845 and growth,” and “development integration” already in progress.
846

847 **4.3.3 Ethics-Focused Reasoning.** The UEQ-A condition showed increased ethics-focused reasoning ($\chi^2 = 23.3$, $p < 0.001$,
848 $V = 0.133$), with 54.9% occurring in UEQ-A compared to 30.8% in UI and 14.3% in UEQ.
849

850 UEQ-A participants emphasized “user well-being and safety outweigh business considerations,” “violating fundamen-
851 tal principles of ethical user interface design,” “undermining autonomy,” and “harmful to user trust.” They referenced
852 “ethical design principles,” “user autonomy,” “protecting users,” and concerns about “manipulative” designs that would
853 “destroy user trust.”
854

855 **4.3.4 Aesthetic-Focused Reasoning.** Aesthetic-focused reasoning showed condition differences ($\chi^2 = 27.2$, $p < 0.001$,
856 $V = 0.144$), with highest prevalence in UI (42.1%) compared to UEQ-A (29.7%) and UEQ (28.2%). UI participants ref-
857 erenced judgments like “clean design,” “visually appealing,” “functional,” “polished,” “attractive,” “beautiful interface,”
858 “minimalistic,” “vibrant,” and “appealing colors.”
859

860 **4.3.5 Business-Focused Reasoning.** Business-focused reasoning showed condition differences ($\chi^2 = 20.8$, $p < 0.001$, $V =$
861 0.126), with highest prevalence in UI (45.3% vs. UEQ 29.1% vs. UEQ-A 25.6%). UI participants emphasized “competitive
862 market” pressures, “revenue potential,” “strategic goals,” “business goals,” “monetization,” “user retention,” “growth,”
863 “market capture,” and “business objectives.”
864

865 **4.3.6 Emotional Intensity.** Emotional intensity showed condition differences ($\chi^2 = 15.1$, $p < 0.001$, $V = 0.107$), with
866 highest prevalence in UEQ-A (47.9%) compared to UEQ (29.0%) and UI (23.1%). UEQ-A participants used stronger
867 emotional language including “extremely poor,” “awful,” “terrible,” “highly unsuitable,” and “definitely.” UI participants
868 used terms like “I HATE,” “unacceptable,” “amazing,” and “love it.”
869

870 **4.3.7 Interface Design Elements.** Interface design elements showed condition differences ($\chi^2 = 17.3$, $p < 0.001$, $V =$
871 0.115), with highest prevalence in UI (39.1%) compared to UEQ-A (32.0%) and UEQ (28.9%). Participants across conditions
872 referenced technical components including “efficient,” “organized,” “ease of use,” “usability,” “clear,” “confusing,” and
873 “navigation.”
874

875 **4.3.8 Conformity Justification.** Conformity justification showed differences across conditions ($\chi^2 = 7.8$, $p = 0.020$, $V =$
876 0.077) but did not reach significance after Bonferroni correction. UI participants (51.6%) most frequently referenced
877 “standard,” “familiar,” “user expectations,” “already in place,” “other social media,” and “platform-level” conventions.

925						
926	4.5 Autonomy-Focused Evaluation Metrics Increase Designer Sensitivity to Dark Patterns					
927	Substantial effects were observed with a 26.2 percentage point difference in rejection rates between No Evaluation Data and UEQ+Autonomy conditions (30.0% vs. 56.2%) and the 1.52-point difference in release tendency on the 0-7 scale. Effect sizes for the primary comparisons were large according to Cohen's conventions: No Evaluation vs. UEQ+Autonomy showed $d = 1.20$ for tendency and $d = 1.13$ for rejection rates.

Interfaces are ordered from largest to smallest difference between No Evaluation Data and UEO+Autonomy conditions, showing the percentage of participants who answered "no" to releasing each interface in their binary release decisions.

information provided, with autonomy-focused metrics leading to more critical assessments. Despite these behavioral differences, decision confidence remained consistently high across conditions, suggesting systematic overconfidence in design decision-making.

Computational text analysis revealed seven of eight justification categories showed condition differences after Bonferroni correction, with effect sizes ranging from small to medium (Cramér's V: 0.107 to 0.299). The progression from no evaluation data to standard usability evaluation to autonomy-focused evaluation corresponded to increasingly critical assessment of interfaces containing dark patterns. Individual interface analysis identified six interfaces with significant sensitivity to autonomy-focused evaluation metrics, with effect sizes ranging from medium to large ($d = 0.55$ to 1.02).

5 DISCUSSION

This study provides evidence that evaluation metrics actively shape design, by triggering ethical sensibility. Through a controlled experiment with 141 UX professionals, we demonstrated that the type of evaluation data provided to designers systematically influences their willingness to approve interfaces containing dark patterns, with autonomy-focused metrics nearly doubling rejection rates compared to no evaluation data (56.2% vs. 30.0%).

5.1 Evaluation Metrics as Design Interventions

Our results challenge the assumption that evaluation tools are neutral measurement instruments. Instead, they reveal evaluation metrics as active interventions that shape what designers notice, consider, and ultimately approve. The

989 stepwise progression in rejection rates—from 30.0% (no data) to 43.9% (standard UX metrics) to 56.2% (autonomy-focused metrics)—demonstrates that providing any user feedback increases ethical scrutiny, but the specific dimensions emphasized in that feedback fundamentally alter design decisions.

990 This finding aligns with literature on measurement's transformative effects [79], but extends it to show how
991 evaluation metrics specifically trigger ethical sensibility. Standard UX metrics like the UEQ, while not explicitly ethical,
992 still increased critical assessment of dark patterns compared to pure UI evaluation. However, autonomy-focused metrics
993 produced the strongest effects, suggesting that making ethical considerations salient through evaluation metrics can
994 effectively guide designers toward more ethical decisions.

995 The practical implications are significant: organizations cannot treat evaluation metrics as passive tools that simply
996 capture designer preferences. Instead, the choice of evaluation metrics becomes a design intervention itself—one that
997 either supports or undermines ethical design goals.
998

1003 5.2 Triggering Latent Ethical Sensitivity

1004 The qualitative analysis of 1,313 professional explanations reveals that evaluation frameworks don't just change what
1005 designers decide, but fundamentally reshape how they think about design problems. When provided with autonomy-
1006 focused evaluation data, 77.7% of participants demonstrated manipulation awareness compared to only 20.7% in the
1007 no-data condition. This represents a nearly 4-fold increase in explicit ethical reasoning.
1008

1009 This transformation suggests that UX professionals possess latent ethical sensitivity that can be activated by
1010 appropriate evaluation tools. Rather than requiring extensive ethics training or external oversight, our findings indicate
1011 that designers are receptive to ethical considerations when those considerations are made salient through their existing
1012 evaluation workflows.
1013

1014 The shift from responsibility avoidance (most common in no-data conditions) to manipulation awareness (dominant
1015 with autonomy metrics) indicates that evaluation frameworks influence not just ethical conclusions but the entire
1016 ethical reasoning process. This suggests that incorporating ethical dimensions into evaluation tools could be a scalable
1017 approach to promoting ethical design practice.
1018

1022 5.3 Designer Overconfidence and Bias Blindness

1023 Our confidence findings reveal a notable disconnect between decision behavior and decision certainty that has important
1024 implications for UX evaluation practice. Despite significant behavioral differences in release decisions across evaluation
1025 conditions—with participants being considerably more conservative when provided with UEQ metrics and autonomy
1026 risk information—participants maintained consistently high confidence in their judgments regardless of the evaluation
1027 framework provided.
1028

1029 This pattern suggests that **designers systematically overestimate their rational decision-making capabilities**.
1030 When presented with interface screenshots alone, participants were highly confident in decisions that were demonstrably
1031 different from those they would make with more comprehensive evaluation information. This confidence did not
1032 decrease when additional UEQ metrics revealed potential usability issues, nor when autonomy risk assessments
1033 highlighted ethical concerns that further influenced their decisions.
1034

1035 The text analysis reveals that evaluation frameworks do not merely influence what designers decide, but fundamentally
1036 reshape how they think about ethical considerations. The shift from responsibility avoidance to manipulation awareness
1037 when autonomy-focused data is present suggests that designers possess latent ethical sensitivity that can be activated
1038 when autonomy-focused data is present suggests that designers possess latent ethical sensitivity that can be activated
1039

1041 by appropriate evaluation tools. This implies that designers may be unaware of how evaluation frameworks shape their
1042 moral reasoning and blind to their own biases.

1043 The overconfidence effect has several critical implications for UX practice. First, designers may develop false
1044 certainty about release decisions based on limited information, potentially leading to premature product releases or
1045 inadequate evaluation processes. Second, high confidence in initial assessments may create resistance to conducting
1046 more comprehensive UX evaluations, as designers may feel their initial judgments are sufficient.
1047
1048

1049 5.4 Interface-Specific Vulnerability to Ethical Evaluation

1050 The interface-by-interface analysis revealed that different dark patterns show varying sensitivity to evaluation frame-
1051 work effects. Content customization, endlessness, and trick wording showed the largest differences between standard
1052 UX and autonomy-focused evaluation, suggesting these patterns are particularly vulnerable to ethical scrutiny when
1053 autonomy considerations are made salient.
1054
1055

1056 This heterogeneity in pattern responses has practical implications for evaluation strategy. Some dark patterns may
1057 be effectively identified through standard UX metrics alone, while others require explicit ethical evaluation dimensions
1058 to trigger appropriate designer concern. Understanding which patterns require which types of evaluation could help
1059 organizations prioritize their evaluation investments and develop targeted assessment protocols.
1060
1061

1062 The finding that 6 of 15 interfaces showed significant autonomy-focused effects after correction suggests that roughly
1063 40% of dark patterns may be specifically vulnerable to autonomy-based evaluation approaches. This specificity indicates
1064 that different ethical evaluation approaches may be needed for different categories of manipulative design. Beyond
1065 manipulation concerns, future work could explore other user-centric ethical dimensions (e.g., privacy, fairness, security)
1066 to see if different patterns respond to different ethical lenses.
1067
1068

1069 5.5 Practical Implications for Design Organizations

1070 These findings have immediate practical implications for design organizations seeking to improve ethical outcomes.
1071 Rather than relying on designer training or external oversight, organizations can incorporate ethical considerations
1072 directly into their existing evaluation workflows through autonomy-focused metrics.
1073
1074

1075 The stepwise progression in critical assessment (30% → 44% → 56% rejection rates) suggests that even standard
1076 UX evaluation provides some ethical benefit compared to pure aesthetic judgment, but autonomy-focused evaluation
1077 provides the strongest ethical guidance. Organizations could implement tiered evaluation approaches, using standard
1078 UX metrics as an initial screen and autonomy-focused evaluation for interfaces that raise initial concerns.
1079
1080

1081 The high confidence across conditions also suggests that designers may not recognize when they need additional
1082 evaluation information. Structured evaluation protocols that require consideration of multiple evaluation dimensions
1083 before release decisions could help mitigate overconfidence effects and ensure more comprehensive ethical assessment.
1084
1085

1086 *5.5.1 Metrics vs. Guidelines: The Power of Empirical Weight.* Our approach differs fundamentally from traditional
1087 design guidelines or ethical frameworks. While design guidelines typically offer prescriptive rules (e.g., ‘avoid deceptive
1088 language’ or ‘provide clear navigation’), metrics carry empirical weight derived from actual user responses to specific
1089 design features. This distinction is critical: when evaluation data shows that users rate an interface as ‘pressuring’ (-1.4
1090 on autonomy scales) or ‘covert’ rather than ‘transparent,’ it provides concrete evidence rather than abstract principles.
1091
1092

Our approach also differs from existing dark pattern measurement tools such as the System Darkness Scale (SDS) [81],
which focuses on directly assessing the ‘darkness’ of interfaces through user perceptions of manipulative design

elements. While such approaches provide valuable insights into dark pattern detection, our framework takes an alternative approach by emphasizing positive autonomy values rather than focusing on negative assessments of manipulation. This distinction reflects a different methodological choice: rather than asking users to identify what is problematic with an interface, autonomy-focused metrics assess dimensions that support user agency and freedom of choice.

Additionally, it integrates with existing UX evaluation workflows that typically emphasize positive user experience outcomes. The approach also provides guidance on what to optimize for (autonomy, transparency, user control), rather than identifying what to avoid. Our autonomy-focused approach can be integrated with standard evaluation methods like the UEQ, allowing deployment within existing organizational assessment processes.

Metrics translate user experiences into quantified insights that organizations can systematically track, compare, and optimize against. Unlike guidelines that require interpretation and can be dismissed as subjective preferences, autonomy-focused metrics provide the same objective, data-driven foundation that organizations already value in business metrics. This empirical grounding makes ethical considerations harder to ignore or rationalize away during design decision-making.

5.5.2 Organizational Constraints and Implementation Challenges. We acknowledge that implementing ethics-focused evaluation frameworks faces significant organizational constraints. Companies may resist incorporating autonomy-focused metrics when such considerations conflict with business objectives focused on engagement, retention, or conversion. Some organizations may view comprehensive ethical evaluation as unnecessary overhead, believing that general ethical sensibility or existing compliance frameworks provide sufficient protection.

Our recommendation for achieving ethical design through evaluation metrics recognizes these realities. We do not suggest that metrics alone can solve all ethical design challenges, nor that organizations will uniformly embrace approaches that potentially constrain profitable but manipulative design practices. Rather, our work provides evidence that when organizations do commit to ethical evaluation, metrics-based approaches can be highly effective at triggering ethical sensibility among design practitioners.

The conditional nature of this approach—requiring organizational willingness to prioritize ethical considerations—reflects broader challenges in corporate responsibility and stakeholder capitalism. However, for organizations genuinely committed to ethical design, our findings demonstrate that evaluation frameworks offer a practical, scalable intervention point for translating ethical intentions into design practice.

5.5.3 Applications in Auditing and Regulatory Contexts. Beyond organizational design practice, autonomy-focused evaluation frameworks could serve as valuable tools for external auditing and regulatory oversight. Current regulatory efforts to address dark patterns face significant challenges in establishing consistent, measurable standards for identifying manipulative design [37, 46]. Traditional regulatory approaches often rely on legal definitions, binary classifications, pattern strategy descriptions, or automated pattern matching that may not capture the nuanced ways manipulation manifests in interface design. Further, 'dark' designers may intentionally obscure manipulative elements to evade detection [46], and develop new patterns faster than regulations can adapt [11].

Our metrics-based approach could provide regulators with empirical tools for assessing interface manipulation that complement existing legal frameworks. Rather than relying solely on expert judgment or user complaints, regulatory bodies could employ standardized user centered autonomy-focused evaluations to systematically assess whether interfaces undermine user agency. When evaluation data demonstrates that users experience an interface as 'pressuring'

1145 or ‘covert,’ this provides concrete, quantifiable evidence of potential manipulation that can inform regulatory decision-
1146 making.

1147 Policy efforts have highlighted the need for technical standards that can bridge the gap between legal definitions
1148 and design implementation [75]. Autonomy-focused metrics could serve this bridging function by translating abstract
1149 legal concepts like ‘informed consent’ or ‘user autonomy’ into measurable user experience outcomes. This empirical
1150 grounding could help address what Gray et al. [37] identify as the lack of ‘universally accepted definitions across the
1151 academic, legislative and regulatory space’ that has limited the impact of dark pattern scholarship on regulatory action.
1152

1153 Additionally, third-party auditing organizations could employ these evaluation frameworks to provide independent
1154 assessments of interface ethics, similar to how accessibility audits currently assess compliance with disability access
1155 standards. Such approaches would enable more systematic, evidence-based evaluation of design ethics while providing
1156 organizations with clear, actionable feedback for improvement.
1157

1158

1159 5.6 Redefining ‘Good’ Design

1160

1161 While there appears to be a resurgence of interest in what constitutes ‘good’ interface design [67, 78], discussions within
1162 the design community about when to break usability for reflection [66] and what is meant by unethical design [51]
1163 relate back to questions of values in design [30, 31]. While values in design work indicate that, depending on context,
1164 different values are emphasized by designers, our work highlights that it is not just designers, but also the incentive
1165 structures and evaluation frameworks they are assessed by, that guide what constitutes ‘good design.’
1166

1167

1168 Hedonic values, with the goal of ‘delighting users,’ have become a prevailing focus within the UX design community,
1169 reflecting a long-standing alignment with business objectives [19]. Designers are rarely free to choose the values they
1170 design for and instead must work with ‘tactics of soft resistance’[84] and use complex rhetorical arguments[69] to push
1171 for values outside of immediate corporate interest, such as ethical design. This analysis of UX evaluation frameworks
1172 shows how the most common tools with business proximity fail to meaningfully advocate for user and broader societal
1173 values. When all that matters is a vague target of user experience, autonomy-focused evaluation frameworks might
1174 help translate ethical values into business risks—the only values management truly cares about [47].
1175

1176

1177 5.7 Limitations and Future Work

1178

1179 This study has limitations that should be considered when interpreting the findings. First, our experiment focused
1180 specifically on dark patterns in social media interfaces. While these represent well-documented unethical design
1181 practices, future research should examine how evaluation frameworks influence decisions about other types of ethically
1182 questionable designs across different domains.
1183

1184

1185 Second, participants evaluated static interface screenshots rather than interactive prototypes. While this approach
1186 ensured experimental control and allowed us to isolate the effects of evaluation data, it may not fully capture how
1187 designers would respond to evaluation frameworks when working with functional interfaces. Future studies could
1188 explore how our findings translate to real-world design processes with interactive prototypes and iterative design
1189 cycles.
1190

1191

1192 Third, our sample consisted of professional designers recruited through Prolific Academic. While we employed
1193 rigorous screening criteria to ensure professional qualifications, the generalizability to other design contexts and
1194 organizational cultures remains to be established. Future research could examine how evaluation framework effects
1195 vary across different organizational contexts, team structures, and design methodologies.
1196

1197 Fourth, our experiment presented evaluation data in a controlled format that may not reflect the complexity of
1198 real-world user feedback. In practice, designers often encounter conflicting or ambiguous user data from multiple
1199 sources. Research examining how evaluation frameworks perform with more realistic, complex data presentations
1200 would be valuable.
1201

1202 Finally, while our study demonstrates that evaluation frameworks influence design decisions, we did not measure
1203 the long-term outcomes of these decisions on actual user experiences. Future research could examine whether designs
1204 approved under different evaluation frameworks lead to different user outcomes in terms of autonomy, well-being, and
1205 satisfaction.
1206

1207 Despite these limitations, this study provides important evidence that evaluation frameworks are not neutral tools but
1208 active shapers of ethical design decisions, opening new avenues for improving design practice through more thoughtful
1209 evaluation system design.
1210

1211 5.8 Future-Proofing Ethical Design for Computational Systems

1212 Our findings have particular relevance as design practice increasingly incorporates computational and AI-driven
1213 approaches. Companies are beginning to utilize automated A/B testing, algorithmic design optimization, and AI-
1214 generated interface elements where metrics serve as key guides for automated design decisions. In these computational
1215 design contexts, evaluation frameworks become even more influential as they directly drive algorithmic optimization
1216 processes.
1217

1218 When aspects of interaction design become automated, the metrics used to guide these systems will fundamentally
1219 shape the resulting interfaces. Our research suggests that incorporating ethical dimensions into these evaluation
1220 frameworks could trigger ethical considerations in computational design systems, ensuring that automated design
1221 processes optimize for user autonomy and wellbeing rather than purely engagement or conversion metrics.
1222

1223 Future work should explore how ethics-focused evaluation frameworks can be integrated into automated design
1224 pipelines, how AI systems respond to multi-dimensional evaluation criteria that include ethical considerations, and
1225 what new challenges emerge when computational systems must balance potentially competing ethical and business
1226 objectives through quantified metrics.
1227

1228 5.9 Alternative Approaches and Scope of Application

1229 Some critics might argue that instead of revealing ethics through metrics, organizations should focus on developing
1230 designers' ethical sensibility directly through training, education, or organizational culture change. We agree with
1231 research suggesting that not everyone possesses innate ethical foresight or expertise [78], making universal ethical
1232 training challenging to implement effectively.
1233

1234 Our metrics-based approach is not intended to replace ethical expertise or comprehensive ethics education. Rather, it
1235 provides a scalable intervention that can complement other ethical design initiatives. Evaluation frameworks can trigger
1236 ethical considerations in the moment of design decision-making, even when designers have not received extensive
1237 ethics training or when organizational pressures make ethical considerations less salient.
1238

1239 This approach may be particularly valuable in large organizations where ensuring consistent ethical training across
1240 all design personnel is challenging, or in contexts where external contractors and consultants participate in design
1241 decisions without deep organizational ethical context. Future research should examine how metrics-based ethical
1242 evaluation performs in combination with other ethical design interventions, and whether different combinations of
1243 approaches provide synergistic benefits.
1244

1249 Additionally, our focus on dark patterns represents one specific domain of ethical design. Future work should explore
1250 how evaluation framework effects extend to other ethical considerations such as accessibility, privacy, environmental
1251 impact, and social justice. Different ethical dimensions may require different evaluation approaches, and understanding
1252 these specifics will be important for developing comprehensive ethical evaluation systems.
1253

1254

1255 5.10 Conclusion

1256 This study demonstrates that evaluation metrics function as active design interventions that systematically shape how
1257 designers approach ethical decisions. By showing professional UX designers different types of user evaluation data, we
1258 revealed that the lens through which we evaluate user feedback fundamentally shapes what we consider acceptable
1259 design practice.
1260

1261

1262 These findings have immediate practical implications: organizations seeking more ethical design outcomes should
1263 carefully consider what evaluation frameworks they employ and how those frameworks highlight or obscure ethical
1264 concerns. The path toward more responsible technology design may lie not just in training designers to be more ethical,
1265 but in designing evaluation systems that make ethical considerations visible and actionable.
1266

1267

1268 6 DATA AVAILABILITY

1269 The datasets from both the UX+Autonomy Evaluation Study with social media users and the UI Release Study with UX
1270 professionals will be made available upon publication through the Open Science Framework [4].

Fig. 8. Interface-specific effects across evaluation conditions. Violin plots show the distribution of release tendency ratings (0-7 scale: 0 = *definitely would not release*, 7 = *definitely would release*) for each interface, with significant differences after FDR correction marked. Dark patterns show varying sensitivity to evaluation framework effects, with content customization, endlessness, and trick wording showing the strongest autonomy-focused evaluation effects.

Table 2. UX+Autonomy Evaluation Study Results: Overall Mean and Item Means per Dark Pattern. Data from Stage 2 user evaluation study (N=126) showing evaluation scores across UEQ and autonomy-focused dimensions. Item Means ≤ -0.75 are shown in purple, and Item Means ≥ 0.75 are shown in teal. Numbers in colored boxes indicated the lowest scoring attribute per pattern. NAG = Nagging, OP = Overcomplicated Process, HAD = Hindering Account Deletion, SBD = Sneaking Bad Default, ERM = Expectation Result Mismatch, FH = False Hierarchy, TW = Trick Wording, TWE = Toyng with Emotion, FA = Forced Access, GAM = Gamification, SP = Social Pressure, SC = Social Connector, CC = Content Customization, END = Endlessness, PTR = Pull To Refresh. Autonomy-focused items designed to assess user manipulation and control, * from UEQ-S, other items and Attractiveness from the full UEQ.
